Abstract

A review of the present situation in particle physics, astrophysics and cosmology is attempted, which emphasises the unity of the subject.
1. Introduction

The twentieth century has been called the century of Science. There have been four standard models which have been developed during the second half of this century. These are:

1) The Plate Tectonics model in geology;
2) The Double Helix model in Biology;
3) The Hot Big Bang model in Astrophysics and Cosmology; and
4) The Standard $SU_c(3) \times SU_L(2) \times U(1)$ model in Particle Physics.

The major development during the last fifteen years has been the realisation that models 3) and 4) have converged. I shall speak mainly about this aspect of the subject in Part I of this talk.

In Part II, I shall concentrate on non-baryonic dark matter and searches for it. There are problems here of the greatest moment, common to both Cosmology and Particle Physics.
2. Historical Gifts

How models 3) and 4) have historically influenced each other may be seen in the following table:

<table>
<thead>
<tr>
<th>Gifts of Particle Physics to Astrophysics and Cosmology</th>
<th>Gifts of Astrophysics and Cosmology to Particle Physics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nucleosynthesis ⇒</td>
<td>Cosmic abundance of $H, D, H^3, He^3, He^4, Li^7$ $\Leftarrow #$ of $\nu &lt; \text{MeV}$ in mass</td>
</tr>
<tr>
<td>Spontaneous symmetry breaking in: 1) the Electroweak unification ⇒</td>
<td>$\Leftarrow$ Temperature dependance of phase transitions $T_c \approx 250 \text{ GeV}, t_{\text{cosmic}} \sim 10^{-12} \text{sec}$</td>
</tr>
</tbody>
</table>
| 2) the Electronuclear unification (grand unification, G.U.T.) ⇒ | 1) $T_c \approx 10^{14} \text{GeV}, t_{\text{cosmic}} \sim 10^{-35} \text{sec}$  
2) Cosmic strings predicted (by GUTS) as seeds of galaxies.  
3) "Paleogeny vs. Neogeny" relevant for the problem of the "Large scale structure of the universe", i.e. did the large scale of the universe get determined by initial fluctuations when the universe was $10^{-35}$ secs old (i.e. in the epoch of electro-nuclear (GUT) breaking)? |
| Inflation, Superstrings T.O.E. (Theory of Everything) ⇒ | Cosmological relics (like monopoles) diluted by inflation |
| Non-accelerator experiments $\nu$-oscillations (MSW-Bethe mechanism) to resolve the missing solar $\nu$ mystery | $\Leftarrow$ 1) Relics: 
Dark matter;  
Wimps (weakly interacting particles);  
Shadow matter and gravitational-wave detection.  
2) $\gamma$-astronomy at very high energies e.g. $\approx 10^8 \text{ GeV}$ from CYGNUS-3X or similar extra-galactic sources.  
3)$\nu$-astronomy with SN87; clues to $\nu$-masses, $\nu$ life-time, $\#$ of $\nu$ species as well as limits on Axion coupling |

TABLE 1

I was at Cambridge when the theory of nucleo-synthesis was worked out by Fred Hoyle and others. At that time I thought that this was as it should be - Astrophysics should naturally receive inputs from Nuclear Particle Physics. When during the 1980s the converse started to happen with the numbers of $\nu$ species predicted by cosmologists (presumably) agreeing with the laboratory determination of this number, then the Particle Physicists sat up. Already during the 1970s, when it was realised that gauge symmetry restoration takes place at a critical temperature $T_c$, and one recalled that such high temperatures (of the order of 250 GeV for the electro-weak transition) had occurred in the early universe in the Hot Big Bang model, most Particle Physicists felt that they had to learn about the early universe and the phase transitions therein.
3. The Three Eras

I shall divide the history of the subject of Astroparticle Physics into Three Eras. Tables 2-6 and particularly the “Remarks” column in the tables will give a description of the Physics situation and the open problems.

<table>
<thead>
<tr>
<th>Era</th>

</tbody>
</table>
| | Massive pyrgons appear, where $m_k^2$ (pyrgon) = $N(e^{2\phi}M^2_{\text{plank}})$ where $N = 1, 2, 3, \ldots$ generically | Tragedy $\Rightarrow$ | Suggested experimental tests for this string theory (T.O.E.) are rather meagre, some of these are: A) extra one or two 2* \footnote{Generically} 
B) fractionally charged dyons, (even of zero small mass) | 1) One loses the uniqueness of the theory, when $d = 10$ descends down to $d = 4$ (there can be more than several million theories in four dimensions) 2) No descent yet gives the standard particle model $SU_3(3) \times SU_2(2) \times U(1)$ uniquely though the spectrum is basically correctly given, as is the \# of generations. (This last \# is a topological invariant in this theory.) |

$\lambda = \text{the cosmological constant; the most outstanding unsolved problem in Astro--Particle Physics: explain in a natural manner why } \lambda_0 \neq 0$  

For low-energy physics, such pyrgons are irrelevant (where only zero compared to Planck mass particles will be kept  

$\lambda \propto M^4_{\text{plank}}$ (in general) radiatively: $\lambda = 0$ for exact (supersymmetry) $\lambda \propto M^4_{\text{plank}}$ if SS is broken at $M_0$. At present $\lambda_0 = 10^{-122} M^4_{\text{plank}}$ empirically

**TABLE 6**
8. The Third Era (continued)

THE LARGE SCALE STRUCTURE IN THE UNIVERSE

1980s REVOLUTION

1. It was previously believed that galaxies, clusters and superclusters of galaxies are uniformly distributed in space.

However, the new picture evolving during the 1980s is that the three-dimensional plots of redshifts are finding clusters of galaxies distributed on the surface of large "empty" bubbles. These have diameters 20 to 50 Mpcs, one to two orders of magnitude larger than the thickness of the surface of the bubbles.

2. It seems that billions of massive stars exploded becoming super novae, the blast waves from these explosions formed the empty bubbles. Galactic clusters formed where bubbles intersected.

3. One must be cautious however.

"Since many of the known highest-redshift objects were found by accident, and in any case their properties have not been uniquely predicted by any physical model, one must recognize that there is difficulty in making credible generalizations from these biased samples about events in the distant universe."

R. Kron
NOTES TO PART I

NOTE 1

TESTS OF INFLATION

1) $\Omega = 1 + 10^{-BIG#}$.

2) Adiabatic density perturbations with the Harrison-Zeldovich spectrum.

3) Expected spectrum of gravitational waves with $\lambda \sim 1$ km up to $10^{28}$ cm. No spectrum of relic gravitational waves $< 1K$.

"In inflationary scenarios, primeval gravitons like any other pre-inflationary relic are exponentially diluted during inflation".

Starobinsky, Turner

4) The above remark about (zero-mass) gravitons may have relevance for any surviving zero-mass shadow matter which may be part of the second $E_8'$ in the heterotic $E_8 \times E_8'$ string theories. Such shadow matter is supposed to interact with normal matter only through its shared gravitational interaction.
INFLATIONARY CHAOTIC COSMOLOGY

According to A.D. Linde (Physics Today, September 1987 issue):

"The orthodox version of inflation assumed it to be a modest variation on the standard hot Big Bang theory. It was still assumed that there was an initial singularity at $t = 0$, that after the Planck time (about $10^{-43}$ seconds) the universe became hot, and that inflation was just a brief interlude in the evolution of the Universe".

This has changed. For example, in Linde's theory of chaotic inflation, consider a field $\varphi$ which satisfies the Einstein-Friedman equations:

\[
\ddot{\varphi} + 3H \dot{\varphi} = -m^2 \varphi \tag{1}
\]

\[
H^2 + \frac{k}{R^2} = \frac{4\pi}{3M_p} (\dot{\varphi}^2 + m^2 \varphi^2) \tag{2}
\]

(Here $H = \frac{\dot{R}}{R}$.)

1. It can be shown that if the initial value of the field $\varphi = \varphi_0 > 1/5 M_p$, where $M_p = M_{Planck}$, the friction term in Eq.(1) makes the variation of the field $\varphi$ very slow, so that one can neglect $\varphi$ in Eq.(1) and $\varphi$ in (2). Making these approximations, one can solve

\[
\varphi(t) = \varphi_0 - \frac{m M_p}{2\sqrt{3\pi}} t
\]

\[
R(t) = R_0 \exp\left(\frac{2\pi}{M_p^2} |\varphi_0^2 - \varphi^2(t)| \right)
\]

where

\[
R(t) = R_0 \exp(\dot{H}t)
\]

and the Hubble "constant" $H$ is given by

\[
H(\varphi) \approx \sqrt{\frac{4\pi m \varphi}{3 M_p}}
\]

2. If the field $\varphi$ is smaller than $1/5 M_p$, the friction term in Eq.(1) becomes small, and $\varphi$ oscillates rapidly near its equilibrium value of zero.

3. For $m$ of the order of $10^{-4}M_p$ this implies that in our simplest model the inflationary domains of the universe typically expand to $10^{108}$ times their original size!

4. After expansion by a factor $10^{108}$ all initial inhomogeneities, monopoles and domain boundaries have been swept beyond the horizon.
The average amplitude of such perturbation generated during a time interval $H^{-1}$ (in which the universe expands by a factor of e) is given by:

$$\frac{\delta \varphi}{\varphi} \approx \frac{H}{2\pi \varphi} = \frac{m}{3\pi M_p}$$

Perturbations of the field lead to perturbations of density that are just right for subsequent galaxy formation if $m$, the mass of the quantum of $\varphi$, is around $10^{-4}M_p$. (But why has $\varphi$ the desirable mass? Is there a “natural” explanation?)
NOTE ON THE STANDARD MODEL OF PARTICLE PHYSICS AND THE ROLE OF FERMI TRANSITION TEMPERATURE $T_\nu \approx 250 \text{ GeV}$

The standard model of today's particle physics describes three replicated families of quarks and leptons. The first family consists of the so-called up and down quarks ($u_L, d_L$) and ($u_R, d_R$) (L and R stand for left and right chirality of spin-1/2 particles). Each quark comes in three colours: red, yellow and blue. There are, in addition, three colourless leptons, ($e_L, \nu_L$) and $d$. Thus this family has 12 quarks and 3 leptons (altogether 15 two-component objects) with $30 \approx 2 \times 15$ degrees of freedom.

The second family has charm and strange quarks ($c, s$) (replacing the up and down ($u, d$) quarks) while the electron and its neutrino are replaced by the muon and its neutrino. Like the first family, there are 15 two-component objects. The third family likewise consists of top and bottom ($t, b$) quarks plus the tauon and its neutrino.

In addition to these 45 (= $3 \times 15$) spin−1/2 two-component objects, there are the 12 Yang–Mills–Shaw gauge spin−1 messengers corresponding to the symmetry $SU_c(3) \times SU_L(2) \times U(1)$ – the photon $\gamma$, $W^\pm$, $Z^0$ and eight (confined) gluons. Nine of these ($\gamma$ and eight gluons) are massless. In addition, there should at least be one physical spin−zero Higgs $H_0$ giving a total minimum degrees of freedom ($118 = 3 \times 15 \times 2 + 9 \times 2 + 3 \times 3 + 1$) for the particles in the standard model. All particles except the top quark and the Higgs in this list have been discovered and their masses and spins determined (even though the colour−carrying quarks and gluons are confined). (In this context, it is worth remarking that CERN data from SppS have confirmed the theoretical (tree diagram) expectation of $W^\pm, Z^0$ masses to within 1%. (Experiments give $81.8 \pm 1.5 \text{ GeV}$ for $W^\pm$ and $92.6 \pm 1.7 \text{ GeV}$ for $Z^0$ masses.) The model is unified: the $\gamma$ and $Z^0$ mix, but the magnitude of the mixing is expressed as a parameter ($\sin^2\theta$) which remains to be fixed by experiment. The unification happens when the temperature is higher than the Fermi mass scale $G_F^{-1/2} \approx 250 \text{ GeV}$ which, according to the standard cosmological model occurred when the Universe was $10^{-12}$ sec. old. Before this phase transition occurred, there were three fundamental forces (electroweak, strong and gravitational). Afterwards, the electroweak force separated into electromagnetism and the weak nuclear force, with $W^\pm$ and $Z^0$ becoming massive.
SUPERSYMMETRY (MATTER-FORCE-SYMMETRY)

Astounding Symmetry Discovered Theoretically around 1974

Astounding because: it connotes symmetry between fermions and bosons: i.e. symmetry between fermionic matter of $\frac{1}{2}$ or $\frac{3}{2}$, (objects which are *individualists* obeying the Pauli Exclusion Principle) and bosonic force messengers of spins-0 or 1 or 2 which are *collectivists* and like to congregate.

MINIMAL (BROKEN) SUPERSYMMETRY MODEL has two Higgs multiplets plus higgsinos.

No evidence has been found yet for the existence of partners of quarks or leptons up to $\approx 50$ GeV. The most crucial open problem in particle physics is to discover if these particles exist (expectedly below 1000 GeV centre of mass energy). As remarked before, there are 2 Higgs doublets in this theory i.e. 3 live Higgs particles $H_1, H_2, H_3$ and $H^\pm$ with $m_{H_2} < m_z$.

The SSC is meeting opposition in the US because alleged of high costs - $5 billion over 5 years of construction. Compare this with the sums of monies already spent on a project like SDI which have amounted to $12.7 billion so far.
1) For the circular accelerators, the bending magnet may be improved by Superconductivity Technology, but the real limitation is due to synchrotron radiation $\propto (E^4)$. The cost and size of the accelerator increase as $E^2$. Here $E$ is the c.m. energy.

2) For linear accelerators, the highest Electric Field gradients $\mathcal{E}$ achievable with today’s technology, are at most around $1/10$ GV per meter. Twenty years hence (when, for example, we may have mastered the technology of laser beat-wave plasma accelerators) the gradient may go up by a factor of 1000 – i.e. $1/10$ TV per metre. This may mean that a 30 km long accelerator would produce center of mass energy $(\sqrt{s}) \approx 10^4 TeV$.

3) Chen and Noble have shown that if one can use longitudinal electron plasma waves in a metal, the electron density is of the order of $10^{22} cm^3$ (versus normal plasma densities of the order of $10^{14} – 10^{18} cm^3$) and we gain a factor of $\sqrt{n} \approx 10^2 – 10^3$ (with the maximum energy limited to $10^5$ TeV, on account of channeling radiation).

To be crazy, an accelerator around the moon may generate $10^6$ TeV; an accelerator around the earth – as Fermi once conceived – may be capable of $\sqrt{s} \approx 10^7$ TeV, while an accelerator extending from earth to the sun would be capable of $\sqrt{s} \approx 10^{11}$ TeV (with $\mathcal{E} \sim 1/10$ TV/metre). In the same crazy strain, for an accelerator to be capable of generating $\sqrt{s} \approx 10^{16}$ TeV (the theoretically favoured, Planck Energy) one would need an accelerator 10 light years long.
The isotropic sky flux
An example of the predictions of $\Delta T/T$ for different assumptions about the nature of the matter content of the universe, particularly the "dark matter" ("C" is for cold particles; "N" is for massive neutrinos.) Note that the single data point shown excludes some models and that measurements at comparable sensitivity, but $\theta \sim 30^\prime$, would exclude most. Also, $H_0 = 75$ km/sec per Mpc, except for $Cl(H_0 = 50)$. (From Bond and Efstathiou, 1984).
PART II

“If all the matter of the universe were evenly scattered ..., and every particle had an innate gravity toward all the rest, ... matter could never convene into one mass ... but it would make an infinite number of great masses, scattered at great distances from one another ... and thus might sun and fixed stars be formed ...”

Newton
The existence of dark matter was speculated upon 50 years ago by F. Zwicky. He showed that the visible mass of the galaxies in the coma cluster was inadequate to keep the cluster bound. Oort showed that the mass necessary to keep our own galaxy together was at least three times that concentrated into the observable stars. In recent years this has emerged as the major open problem of Cosmology and Particle Physics.
The Andromeda Galaxy M31 is shown with, superimposed on it, the rotation velocity of neutral hydrogen, inferred from 21 cm line radio studies. The rotation curve remains 'flat' even beyond the optical outer limits of the galaxy, implying that the outlying gas is 'feeling' the gravitational field of dark matter around the galaxy. (Courtesy of Morton Roberts.)
DARK MATTER (continued)

Define $\Omega = \rho / \rho_{\text{critical}}$ where $\rho_{\text{critical}} (= \rho_c) = \frac{3H^2}{8\pi G}$

Empirically $\Omega_{\text{photonic}} = 3 \times 10^{-5} \frac{T}{2.7K^2} \frac{1}{h_0^2}$ where $H_0 = h_0 \text{ km/sec/MPC}$ $\Omega_{\text{baryon}} \approx .014$

First hypothesis:

$\Omega_{DM} = \Omega_{\text{baryonic}} = .014$ (At most this could be pushed up to $\sim .15$. The limitation comes from the abundance of $H^2, He^3, He^4, Li^7$)

Baryonic Dark Matter if it exists could be in the form of:

1. White dwarfs
2. Neutron Stars
3. Black holes
4. Jupiters

Second hypothesis:

$\Omega_{DM} > \Omega_{\text{baryonic}}$

At best one may motivate empirically, $\Omega_{\text{spiral galaxies}} < 30$ MPC + $\Omega_{\text{group of galaxies}} < 30$ MPC = .2 ± .1

We must then assume that there is dark matter such that

$\Omega_{\text{smooth}} = .7 + .1$ to make up $\Omega_{\text{total}} = \Omega_{\text{smooth}} + \Omega_{\text{spiral galaxies}} = 1 \rightarrow$ respecting the inflationary hypothesis

---

TABLE 7
10. If Dark Matter Is Not Baryonic, What Is It?

"Not only is man not the Centre of the universe physically (Copernicus) or biologically (Darwin) but we and all we see are not even made of the predominant matter variety in the universe."

Martin Rees

(If dark matter is not baryonic).

There are three classes of Dark Matter candidates, Hot, Warm and Cold:

10.1 HOT DARK MATTER PARTICLES (LIKE NEUTRINOS) STILL IN THERMAL EQUILIBRIUM:

1) Cosmological number density comparable to microwave background ⇒ i.e. mass ≈ few tens of eV;

2) Fluctuation Spectrum. The spectrum of fluctuations at late times in a hot dark matter model is controlled mainly by free streaming;

3) Free streaming destroys any fluctuation smaller than supercluster size. This gives top-down scale structure if dark matter is hot, i.e. galaxies and clusters form after superclusters;

(This is not the case for warm or cold dark matter.)

4) If $H_0 = h_0 \times 100 \text{ km/sec Mpc}$;

$$\Sigma_\nu (1/2 g_\nu) M_\nu \approx 100 \text{ eV} \frac{L}{r_\epsilon} h_0^{-2};$$

Thus, required neutrino mass,

$$M_\nu \sim (25 \text{ to } 100) \text{ eV/species.}$$

Present experimental limits

$$M_\nu < 35 \text{ MeV, } M_{\nu_e} < 250 \text{ KeV,}$$

$$M_{\nu_e} < 18 \text{ eV (Zurich), } 23 \text{ eV (Los Alamos), } 30 \text{ eV (Tokyo), } \approx 19 \text{ eV (ITEP)}$$

from SN 1987a

$$M_{\nu_e} < 15 \text{ eV.}$$
10.2 POTENTIAL PROBLEMS WITH *HOT* DARK MATTER

1) Galaxy formation presumably took place before $z = 3$. If QSOs are associated with galaxies, as suggested by galactic luminosity around nearby QSOs, abundance of QSO at $z > 2$ is inconsistent with "Top-Down" neutrino dominated scheme.

2) X-rays from the shock-heated pancakes are missing.

"These (serious) problems, however, may not be fatal for the hypothesis that neutrinos are the dark matter."

*J. Primack*
10.3 CANDIDATES FOR WARM DARK MATTER

1) Supersymmetric partners, like the light gravitino $M = M_{SUSY}^2 M_{pl}^{-1}$ (spontaneous SS breaking) so $M \approx 1 \text{ keV}$ if $M_{SUSY} \approx 10^6 \text{GeV}$.

2) A hypothetical light right-handed neutrino $\nu_R$ (predicted, for example, by GUT SO(10)) could be a warm–dark matter candidate but Particle Physics provides no reason why $\nu_R$ should be light.

10.4 CANDIDATES FOR COLD DARK MATTER (The favourite model of particle physicists)

1. *Quark Nuggets* (Witten)
   
   i.e. Ultra Dense Matter with $\#u \sim \#d \sim \#s$

2. *Massive Neutrinos*
   
   Few GeV.

3. *Axions*
   
   Light scalar Goldstone bosons needed to conserve CP in strong nuclear interactions.

4. *Supersymmetric Relics*
   
   Lightest one (perhaps photinos of a few GeV in mass) expected to be stable due to the conservation of $R$ quantum number (which in general $= -1$ for the new supersymmetric partners).

10.5 CONSTRAINTS ON AXION MODELS

1. *Laboratory Experiments*
   
   (axion $\rightarrow 2\gamma$, and assuming the $\#$ of axions $\approx 10^3$ times $\#$ photons)
   
   $$ f_a > 10^3 \text{ GeV} $$
   
   (where $f_a$ is defined from the Lagrangian term $f_a^{-1} \phi_a F_{\mu\nu} \tilde{F}_{\mu\nu}$ and $\phi_a$ is the axion–field)

2. *Standard Solar Model*
   
   $$ f_a > 10^7 \text{ GeV} $$
3. Solar Axio — Electric Effect

search in underground Ge detector (Ahlen et al.)

\[ f_a > 0.5 \times 10^7 \text{ GeV} \]

4. Red Giants, White Dwarfs, Neutron Systems

\[ f_a > 10^9 \text{ GeV} \]

5. Supernova 1987

new limit \( f_a > 10^{11} \text{ GeV} \)

6. Cosmological Limit

\[ f_a < 10^{12} \text{ GeV} \]

Thus the window on the axion is fast closing.
11. Cosmic Strings In Relation to TOE Strings

1. Any string produced before inflation is exponentially diluted.

2. Cosmic strings may be superconducting, large currents ($\approx 10^{20} A$) release energies $\approx 10^{60}$ ergs; trigger explosive galaxy formation.

3. "It is argued that, in fundamental string theories, as one traces the universe back in time, a point is reached when the expansion rate is so fast, that the rate of string creation due to quantum effect balances the dilution of the string density due to the expansion. One is therefore led into a phase of constant string density and an exponentially expanding universe. Fundamental strings therefore seem to lead naturally to inflation."

    Turok
12. Laboratory Tests For Dark Matter A.

1) Axion detectors $a \rightarrow 2\gamma$ in an inhomogeneous magnetic field find $m_a \leq 10^{-5}$ eV;

2) Bolometric detectors $\rightarrow$ with $\sigma_{\text{scatt}} \sim \sigma_{\text{weak}}$ deposit keV energies;

3) Monopole detectors (like the MACRO) in Gran Sasso (which is a truly impressive laboratory).

"Laboratory schemes for detecting a halo population of exotic particles most worthwhile and exciting high-risk experiment in Physics or Astrophysics (as important as the discovery of microwave background in the 1960s)."

M. Rees

Mean velocity of halo particles relative to the detector would have an annual variation (because of the earth's motion around the sun). The most important part of the test:

The variation in amplitude $\sim$ few % and peaking in June would provide evidence against spurious background.

B. A variety of detection principles such as superheated superconducting granules (SSG), bolometers, ballistic phonons, rotons in superfluid helium, transition edge thermometers and superconducting tunnel junctions have recently been (theoretically) investigated for SSG devices. Since the involved energy quanta for these detectors are so much smaller ($\sim 1/1000$ eV for breaking a Cooper pair in a superconductor for example) than for conventional ionisation ($\sim 20$ eV) or semiconductor ($\sim 1$ eV) detectors, in principle very low energy thresholds and very good energy resolution can be expected ...

"For solar neutrino detection, the coherent neutral current neutrino-nucleus scattering method is used. This method has the advantage that the cross-section is three orders of magnitude larger than the cross-section of other processes, like, for example, inverse beta-decay. Thus, an SSG detector with a weight of a few kilograms would measure the same event rate as a multi-ton detector based on other processes. The second advantage is that the SSG detector responds to all neutrino flavours equally."

**TABLE 8**
13. Envoi

I started this paper by speaking of the four standard models elaborated during this century. In closing I would like to mention how the biological standard model is being influenced by recent advances in particle physics.

It is well known that one of the basic problems in biology is the left-handedness of naturally occurring amino-acids and the right-handedness of sugars. In the laboratory these are produced as racemic mixtures with left and right molecules equal in numbers. (Thalidomide was one such laboratory racemic mixture which led to tragic results for the new-born babies.) A happier case is that of penicillin which splits open the D-type skins of bacteria.

In this respect it has recently been suggested (see, S. Mason, New Scientist, 19 January 1984, for a review) that a clue to a solution of this mystery may lie in electroweak unification and the appearance of the neutral (left-handed) weak interactions in the chemical Hamiltonian. This is shown to make for a small preponderance of left-handed amino-acids (and right-handed sugars) – 1 part in $10^{17}$. This preponderance, plus the longevity of the biological epoch, apparently explain the occurrence in natural environment of the stated forms of chiral molecules.
14. Conclusions

14.1 OPEN QUESTIONS BEYOND THE STANDARD MODEL

PARTICLE PHYSICS

1. The status of the standard model? What lies beyond it, GUT or strings?
2. Are there supersymmetric particles?
3. The dark matter, does it exist? Its composition? Is it cold?
4. Are quarks & leptons composite? (not elementary at energies in excess of 1000 GeV)
5. Do gauge-bosons like $W_R$ (mediating weak $V + A$) or $SU_4(3)$ (strong axial gluons) or string-inspired $Z^0'$ exist? likewise the existence of axions, familons, majorons at a new mass scale $\approx 10^{11}$ GeV. Are there present Goldstone particles?
6. $q$ masses, their oscillations; Do $\nu_R$ exist? Solar $\nu$ puzzle? Is it a puzzle at all?
7. The near zeroness of the cosmological constant

14.2 OPEN PROBLEMS IN COSMOLOGY

1. The dark matter. Does it exist? Its composition?
2. Photon-to-baryon ratio

   Grand unification theories suggest that this ratio can be explained in terms of baryon non-conservation processes, and GUT parameters. Is that so?
3. Fluctuation spectrum ($\Delta \rho/\rho$)
4. The near zeroness of the cosmological constant.

I shall conclude this brief paper by repeating Glashow's picture of the Universe. This should show "generalized" gravity as it emerges from string theory as the Theory of Everything (T.O.E.) uniting all things "great and small".

I am indebted to John Ellis, Martin Rees, Dennis Sciama and Donald Lynden-Bell for help with cosmology.
